Finally, the advanced application module of digital twin microgrid is prospected to provide lessons and references for the construction of digital twin microgrid. 1. Introduction

What is digital twin technology?

Digital twin technology utilizes sensors, big data, artificial intelligence and other technologies to establish the mirroring from physical space to virtual space, and it is an effective way to analyze the evolution law of dynamic behavior of key equipment and power systems, and propose optimal control strategies.

What can DTs do for microgrids?

DTs are powerful tools capable of improving the simulated efficiency of multiple aspects of microgrids with high-performance IoT communication, rich modeling exchanges, and AI-based optimization. The article highlights new features and capabilities that DTs can add to microgrids:

How a microgrid can predict PV and wind power?

Through big data and other deep learning intelligent analysis methods, the microgrid will be able to make active and accurate prediction of PV and wind power in the medium and long term, short term and ultra short term, by combining PV and wind resource characteristics and historical power generation data. 6.2.

Leading researchers at the Singapore Institute of Technology have developed a digital twin of the Punggol Campus microgrid in Singapore. The digital twin looks to improve the resilience and efficiency of microgrids and predictive maintenance to prevent equipment faults and issues such as power surges.

A microgrid digital twin (MGDT) refers to the digital representation of a microgrid (MG), which mirrors the behavior of its physical counterpart by using high-fidelity models and simulation platforms as well as real-time bi-directional data exchange with the ...

The establishment of MGDT comprises a digital twin of each section of the microgrid. For the formulation of DT, the planning layout includes data from each unit of MG that needs to be collected to develop a model, model adaptation, algorithm formulation, bi-directional exchange of data between the physical and virtual model and model validations.

This study proposes the use of a digital twin (DT) for the energy management of NMGs in the distribution system and can provide real-time dispatch updates in the schedule of conventional generators, FC and BESS in both isolated and grid-tied modes. The networked microgrids (NMGs) have become one of the better means of improving the resiliency and reliability of ...
